Second Contribution to a Knowoledge of the Miocene Fauna of Oregon. By E. D. Cope.
(Read before the American Philosophical Society, Decomber 5, 1879.)
Two contributions to the present sulject have leen heretofore made by the writer, viz., in the Proceedings of the American Philosophical Society, for November, 1878 ; and in the Bulletin of the U. S. Geological Survey of the Territories for February, 1879. In the latter article thirty-eight species of vertebrata were enumerated as having been diseovered in the Truckee beds of the White River formation of Oregon, of which all but one were mammalia.

I have since conducted explorations in that region, the expeditions being mostly under the direction of Jacob L. Wortman. This gentleman has obtained a great many specimens, several of which indicate new species, which it is the object of the present article to describe. In addition to these discoveries, Mr. Wortman has sent remains of Lacertilia and Ophidia, orders previonsly unknown in Oregon. I had discovered them in the White River formation in Colorado in 1873.
IIesperomys nematodon, sp. nov.
This rat is represented by a beautiful skull, discovered by Prof. Thomas Condon, of Engene city, and hy several jaws, and other fragments subsequently found by Mr. Wortman.

The frontal region is not contracted as in Eirmys elegans and Friber zibethicus, but the supereiliary ridges are well separated from ench other, as in IIesperomys americanos. 'The frontnl and posterior masal regions are slightly concave in transverse section. The mohars display tubereles on one side, and crescents on the other, the former being external in the superior series. The first sujuerior molar has an additional tubercle at its anterior extremity. The incisors have a transverse anterior fiec, which is divided by several delieate ridges.

Length of superior molar series, .0065 ; length of first superior molar, .0028 ; interorbital widh, 0042 . Length of inferior molar series (specimen No. 2), .0064; length of first molar, . 002; wilth of incisor, . 001 ; depth of ramus ut second molar, . 004 .
Sciules voletmant, sp. hov.
Like the S. relictus, of the Colomado White River heds, this is a rare species, being only represented hy a mandibular ramms in my collection. This part is remarkible for its depth as compared with its length ; nud the base of the cormold proress has manterior position. It rises opposite the pomberior part of the third molar, and its anterior homder desconds lon point Junt below the posterior part of the flest mohar. The finferior border of the masteterle fossat is a prominent edre, which deseends below the inner inferior margin of the ranus. The molare diminish regularly in size forwarlas: thele ceowns are basinshamed, with the materior angle of the er-
ternal border elevated, and the inner border notehed medially. Incisor compressed.

Length of inferior molar series, .010 ; antero-posterior diameter of first molar, . 0024 ; length of fourth molar, . 003 ; depth of ramus at diastema, .005 \% ; depth at third molar, .009..

This species is considerably larwer than the S. relictus. It is dedicated to Jacob L. Wortman, of Eugenc, Oregon, a successful explorer of the palcontology of that State.
Paciculus insolitus, gen. et sp. nov.
Char. gen. Superior molars three, rooted. Enamel forming three entrant loops on the external face of the crown, and one on the internal face.

While the number of the superior molars of Paciculus is as in the Murida, the details of their structure is much as in Dasyprocta and Stereofiber. But one species is known.

Char. spec. Size small. Molars regularly and rapidly diminishing in size posteriorly. Imer enamel loop turned forwards ; the external straight and transverse, excepting in the first molar, where the anterior column of the tooth is extended forwards, and the anterior loop is turned back wards.

Length of superior molar series, .006 ; length of first molar, . 0021 ; width of first molar, . 0018 ; length of third molar, . 001.
Canis lemur, sp. nov.
This species is represented by several crania in my possession. It is the smallest of the geaus yet discovered in the Miocenc formation of Oregon. It is characterized by the contracted proportions of the muzzle, the width of the front, and the large size of the eyes. The postorbital process is only a short angle. The superior border of the temporal fossa is triceable from the postorhital process. Those of opposite sides embrace a smooth sagittal area of an elongate ureeolate form, and unite posteriorly in a very short crest. The species is finther chameterized by the large size of the first superior tubereular molar, which with the second, has a distinct imer cingular border, and median tuberele. The superior sectorial is short, and its inner cusp is anterior.

Some mandibles probably belonging to this species exhibit posterior cutting lobes on the third and fourth premolars. The blades of the sectorial are very short, and the heel large and wide. The tubercles of the tubercular are large.

Length of cranium to front border of orbit, M. . 0525 ; eleration of oceiput, . 058 ; length of superior sectorial, . 007 ; length of first tubercular, .0058 ; width of first tubercular, .0078 ; width of second tubereular, .005 ; length of secoud tubereular, .0035 ; interorbital width of seeond specimen, .0056 ; length of inferior dental series, .048 ; length of sectorial, .008 ; length of heel of sectorial, . 003 5 ; leugth of inferior tubercular, . 00.5; depth of ramus at sectorial, . 0105 .

This species is smaller than Cunis gregurius, and diflers from both it and the C. cuspigerus in the larger orbits, more contracted muzzle, and in the distinct superior border of the temporal fossa, ete.

The dog which I referred to the genus Enhydroogon (Cope) under the name of $E$. basilatus, probably belongs to another genus. Portions of the maxillary bone present the dentition of Ieticyon, viz., P-m. 4, M. 1, thus differing from Enhydrocyon, which possesses P.m. 3; M. 2. As there are but three premolars in the inferior series, this species camnot be referred to Icticyon. but must be accepted as typical of a new genus. This I propose to call Hyœnocyon. It resembles Hyœence more nearly than any genus yet discovered in North America, but probably belongs to the Canidce.

## Amphicyon entoptychi, sp. nov.

This rather small species is represented by a skull which lacks the extremity of the muzzle and the mandible, and has its parietal region crushed.
The superior premolar teeth are rather short in anteroposterior diameter, while the tubercular molars are relatively large. There are no posterior lobes on the former; the internal and external cingula are well developed in the first and second of the latter. The third tubercular is about as wide as the second is long. The sagittal crest is only distinct on the posterior part of the parietal region. Estimated length of skull, M. . 110 ; length of superior molar series, .041 ; length of true molar series, .016 ; length of first tubercular, . 0075 ; length of second tubercular, . 0.55 ; width of second tubercular, .0074 ; length of third tubercular, .0036 ; width of third tubercular, 052 : Length of sectorial width between anterior external angles of first tuberculars, . 030 .

The teeth of this splecies are about half the size of those of $A$. vetus Leidy. Auchaleurus debilis Cope.

American Naturalist, 1879, p. 798a, December.
Char. gen. Dentition, I. $\frac{3}{3} ;$ C. $\frac{1}{1} ; \mathrm{P}-\mathrm{m} . \frac{1}{3} ; \mathrm{M} . \frac{1}{3} ;$ mandible with the unterior face of the sympliysis separated from the lateral face by an angle which is not produced downwards. Superior sectorial without anterior lobe ; inferior sectorial with heel. The characters place Archuplurus at the base of the Fe lide, slowing that it is the most generalized form yet known, and about equally related to the feline and Macherolont series.

Char. specif. General structure of the jaws weak. Superior canine small, little compressed, with an acnte posterior edge which is not serrilate. First premolar in each jaw one-rooted ; second inferior premalar harge ; sectorials large, clastemata very short. Alvenhar border below the inferior sectorial and mbercular teeth everted, forming a large ussenns ebllus, whifh has a free inferior and posterior margln, the latter rising into the hase of the coronoid process. Zygomath slender ; postorbital processes little prominent ; front wide, convex tmasversely.
J.ength of cramim, M. . 200 ; superciliary wilth, . 052 ; zygomatic widh, . 124 ; length from orbit 20 superior inclsors, . 066 ; length of supertor secto. rinl, .023; length of inferior molar serjes, . 061 ; diameter of superior cimine, .012. Abont the size of the panther, or of the Nimeraves brachyops.
 unique in tho orter of Oimaioore. It is evidently a provision mganast the weaknens of the mandibular rami, at the point of greatest strain.

## Hoplopioneus platycoris Cope.

American Nuturulist, 1870, p. 798b, December.
This is the largest sabre tonth discovered in North America. It was twice the bulk of the $H$. primceoves Leidy, and differs from that species and the II. occidentalis in the relatively larger size of the premolar teeth, which are less obliquely placed than in the latter. The first superior premolar is very small. The canine is large and compressed as in the species of Muchorodus, and has serrulate posterior and anterior cutting edges. Inferior incisors with conic crowns. The symphysis is very deep in consequence of the large development of the inferior flares for the canines. Sagittal crest making a steep angle witlr the front.

Total length of cranium, M., .280; zygomatic width, .192; length from orbit to superior incisors, .095 ; length of inferior sectorial, .025 ; of inferior sectorial, .022 ; length of inferior molar series, .05 ; ; length of crown of superior canine, .060 ; width of superior canine at base, .026 . This skull is less than one-sixth smaller than that of the Bengal tiger (Uncia tigris).
Cinenohyus decedens, gen. et sp. nov.
The characters of this genus will be best understood by comparison with those of the two other genera of suilline animals which occur in the same formations.

Premolars three, a wide diastema between the anterior one and its successor. .......................................... Chanohyus.
Premolars four ; dinstemata before and behind the first... Thinolyys.
Premolars four, in a continuous series..................... Pulcochorrus.

It is then apparent that Cheenohyus differs from Dicotyles in faving the diastema behind the anterior premolar instead of in front of it.

Cher. spec. This hog is represented in the collection of Prof. Condon at Eugene City, Oregon, by the anterior part of a cranium, which includes both maxilhry bones. Its size is a little less than that of the Dicotyles torquetus. The series of maxillary teeth is slightly convex externally; and the teeth diminish rapidly in size anteriorly. The difference in dimensions between the first and last true molars is mueh greater than in the other suillines of this period known to me. The external tubercles of the the molars are somewhat flattened externally, and a distinct cingulum passes entirely round their external bases. The first superior premolar has one root, the other premolars possess two.

I suspect that the Dicotyles hesperius of Marsh helongs to Chanohyus. It, differs from the C. decedens in its materimlly smaller size. According to Marsh, it is considernbly smaller than his Thinohyus socialis, which is about as large as the $C$. decelens.

Discovered by Prof. Condon in the region of the John Day river.
Timnohyus tricilences, sp, nov.
Represented by the greater part of the maxillary and mandibular bones of both sides, with teeth.

There is a diastema behind the second inferior premolar, about equal in extent to that ln front of it, which is twice as wide as the one in front of the first premolar. The first and second premolars have but one root, while the two others have two. The first superior premolar is close to the canine, and has but one root; it is separatel by $n$ diastema from the second. The latter has one root, and is near the third, which has two roots. The third and fourth superior premolars have each one eompressed external, and one internal lobe. That of the third is lower and is pressed against the external. It is continued as a ridge posteriorly, enclosing a shallow basin with the external tubercle.

The true molars of both jaws have the intermediate tubereles well developed. The external tubereles of the superior molars are not flattened, and have a low cingulum surrounding their bases. Surface of enamel nearly smooth. Length of true molar series of upper jaw, M. . 046 ; of last superior molar, .017; width of do., .013. Diameter of first true molar, anteroposterior, . 012 ; transverse, .011. . Length of posterior three premolars along base, .028 ; of diastema, .011 . Length from inferior canine to third inferior premolar, . 028 ; length of diastemanterior to scoond premolar. . 008 ; do. of diastema posterior to second premolar, . 007.

This is the species I formerly called Palcochorus condoni* Marsh (Platygonus Marsh). That species belongs to the Loup Fork fama, and not to the present one. Some teeth which probably pertain to it in Prof. Condon's collection, exhibit the peculiarity of not possessing any basal cingula on the molars of cither jaw.

From the fact that Pomelt implies that some of the species of Patcocheerus present a cliastema, I have referred the Thinohyus of Marsh to it as a synonym. $\ddagger$ Pomel's genus was, however, established on a species ( $l$ ' typus) which has no diastema, hence Thinolyus is probably to be preserved.

This species is about the size of the Thinohyus lentus of Marslı, and agrees with his descriptions in several respects. There appears, however, to be a material difference between the specimens in the relations of the inferior premolars. Marsh deseribes a mueh more considerahe diastema in front of the flrst premolar, and does not mention the one behind the seeond premolar. I munequainted with a second species of the genus of about the same size, in which there are bat two diastemata, viz, one before and one behind the first premolar, and I suppose this one to resemble the T. lentus. Specimens of this character are in my collection, and I have seen one in thint of Prof. Condon.
Patiabochamus sumaquans, sp. hov.
This suilline is representel by an entire crambun which was discovered by Prof. Comdon. It indieates a species of the size of the Dirotyles forquatus, and smatler than the Thinolyus trichermes.

The first erne molar is mot disproportionately smafler than the third ; met

[^0]there is a distinet cingulum at the external base of the superior true molurs. The external fices of the external tubereles of these teeth are somewhat flattened. The first premolar has one root, the others have two. They are equidistant and not very closely crowded.

Several suillines are described by Marsh and Leidy, either imperfectly or from imperfect material, so that I have had some difficulty in determining my specimens. The $D$. hesperius of Marsh is probably, as above observed, a Chcenohyus. I have specinens agrecing with Marsh's description of Thinolyus socialis. They belong to an animal of the size of the Cherohyus decedens, but the superior molars have no basal cingulum. Its generic position is yet uncertain. Other specimens agree in characters with the Dicotyles pristinus of Leidy, with which Thinohyns lentus of Marsh agrees in size. In this hog there is no diastema in front of the third inferior premolar, so that it is clearly distinct from the Thinohyus trichonus of the present paper.
Merycopater guiotianus Cope.
Having obtained several crania of this species, I can give the characters of the genus Merycoputer * more fully than hitherto. Dentition; I. $\frac{1-3}{3}$; C. $\frac{1}{\frac{1}{2}}$ P P-m. $\frac{1}{4}$; M. $\frac{3}{3}$. A diastema ahove and below ; fourth superior premolar with two external crescents ; fourth inferior premolar identical in form with first true molar ; the first inferior premolar functionally the canine. Orbit open posteriorly; no facial fosse or vacuities.

This genus is Agriochcerus, with a considerable diastema, and very much reduced superior premaxillary teeth. In my best preserved cranium there is no alveolus for the first ; that of the second is rudimental, and that of the third is small. The premaxillary bones are very small and distinct from each other. The enlargement of the cingula represents the posterior internal tubercle of the fourth superior premolar, so distinct in Coloreodon.

The deficiency in superior incisors is an interesting approximation to true ruminants not heretofore observed in Oreodontidie. I have found the inferior incisors deficient in the genera Cyclopidius and Pithecistes.
Coloreodon ferox, gen. et sp nov.
Char. gen. Deutition, I. ?; C. ${ }^{1}$; P-m. ${ }^{3}$; M. ${ }^{3}$; a wide diastema above ; the first inferior premolar functionally the canine. Last superior premolars with two external and two internal crests Orbit open posteriorly; no faeial fossib or vacuities. The genus differs from Agriochorus in the wide diastemata, presence of but three superior premolars, and two inner tubereles of the fourth premolar.

I possess two species of this new genus, which are represented in my collection by crania without premaxillary bones and mandibles.

Char. specif. Size of Oreodon culbertsoni. Maxillary bone excavated above the diastema, the superior border of the coneavity extending nearly to the base of the zygoma. Zygomatic arehes expanded, their external face concave below the orbit, and plane posteriorly. Saggital crest very

[^1]high, dividing anteriorly into two ridges, which diverge widely, and terminate at a point opposite the postfrontal process. The space enclosed in their angle is plane. Space between supraorbital formina convex.

The posterior internal tubercle of the fourth premolar is much smaller than the anterior; the inner basal tubercles of the second and third are subposterior and acute. The length of the diastema is equal to that of the premolar series. The enamel of the molars is wrinkled. The canines are robust.

Estimated length of skull, M. . 200 ; length of superior molar scries, .066 ; of diastema, 028 ; diapheters of second true molar, - anteronosterior, .016 , transverse, .017 ; width of palate at do., . 033 ; interorbital width, . 060 .

The strongly developed crests and wide zygomata of this animal, to gether with the large canine teeth, evidently indicate that it was a formidable antagonist even for the Carnivora of its time.

Discovered by Charles H. Sternberg.

## Coloneodon macrocerifalus, sp. nov.

This Oreodont is considerably larger than the C. ferox, being of the size of the Eucrotaphus major, white the former equals the Oreodon culbertsoni. It also differs from its congener in the relatively longer and narrower frontal region. The sagittal crest is elevated, and divided into two crests opposite the posterior part of the zygomatic fossa. These branches are nearly stmaight, and diverge at an acute angle, terminating above the postorbital processes. They enclose a deep concavity, which is continuous with the front anteriorly. In C. ferox these crests diverge much more abruptly and widely from a more anterior point, and enclose a much smaller concavity. The suprorbital formmina are close together and are separated by a small protuberance of the middle line. The parictal walls of the temporal fossit are rugose. The posterior tubercle of the fourth premolar is well developed, while a single tubercle is present on the preceding premolar.

Length of cranimn from inion to above superior canine. M5. .230; length from superior canine postorbital angle (axial), . 124 ; length from junction of crests to supriorbital foramina, . 060 ; interorbital wilth, . 072 ; length of lases of the molars except the hist, . 050 ; length of three premolars .027 . Length of diastema, . 030 .

From the North Furk of John Day River; found by J. L. Wortman.
